Chapter 1

Introduction

This project is realized completely in PL (Programmable Logic).

The sampling of the data is performed using the ADAU1761 chip of the zedboard. It is a coder / decoder that samples the voltage level coming from the line in, and can also output it on the line out and do all sorts of transformation. The process of sampling has been facilitated by the use of the interface developed by Mike Field [1]. It provides 24 bit samples at 48kHz.
